

# Why are capacitors installed in distribution boxes

## Overview

Capacitors are essential components in electrical distribution systems, primarily used to improve power factor. By offsetting the reactive power consumed by inductive loads like motors and transformers, capacitors enhance system efficiency, reduce losses and improve voltage. Various common techniques exist for the installation of capacitors on distribution lines: Series connection: In this approach, capacitors are directly linked in series with the load. The capacitor usually consists of two conductors separated by an insulating substance. Among other materials which may be used, a capacitor can be made of aluminum foil separated. Should the voltage on a circuit fall below a specified level for some reason, a device called a capacitor can momentarily maintain the voltage at line value. " These elements are formed from multiple layers of aluminum foil (conductors) and polypropylene film (dielectric) wound together. Let's start with the most common.
